Gene Summary	This gene encodes a member of the bone morphogenetic protein family which is part of the transf orming growth factor-beta superfamily. The superfamily includes large families of growth and diffe rentiation factors. Bone morphogenetic proteins were originally identified by an ability of deminer alized bone extract to induce endochondral osteogenesis in vivo in an extraskeletal site. These pr oteins are synthesized as prepropeptides, cleaved, and then processed into dimeric proteins. Thi s protein may act as an important signaling molecule within the trabecular meshwork and optic ne rve head, and may play a potential role in glaucoma pathogenesis. This gene is differentially regul ated during the formation of various tumors. [provided by RefSeq
